Host Website on AWS using S3 bucket

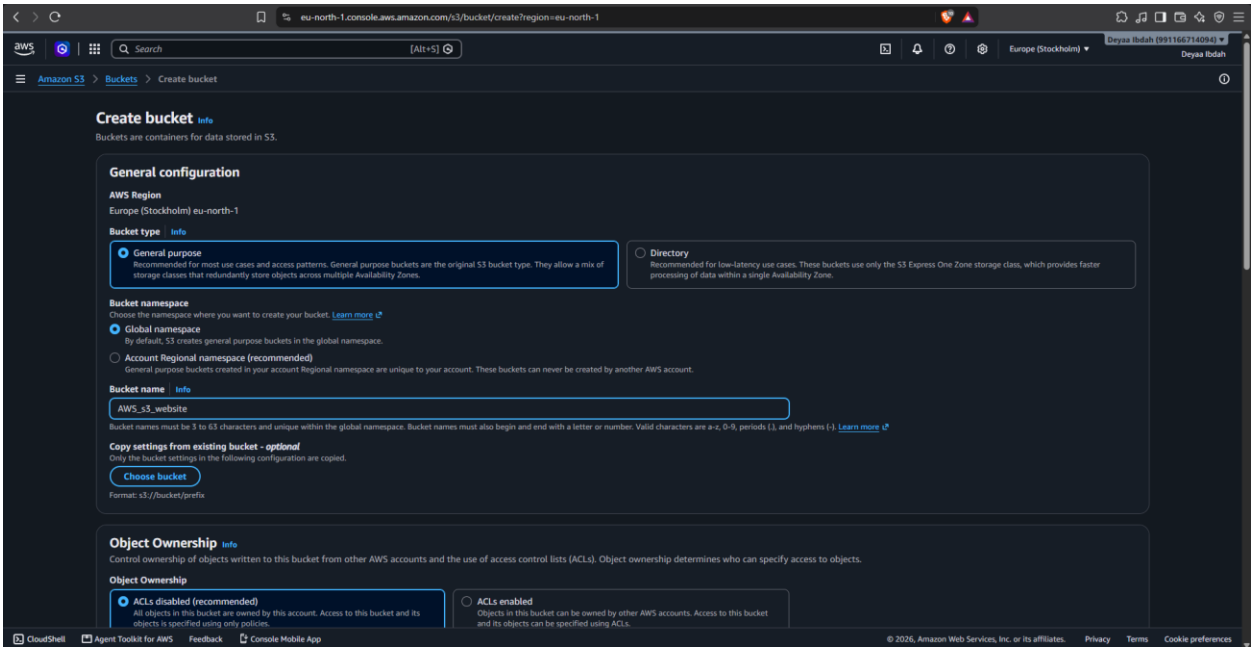

Hi in this project we will get started with AWS and take a series of hands-on project that help in host a static website

First thing we will use AWS S3 bucket

to store website files

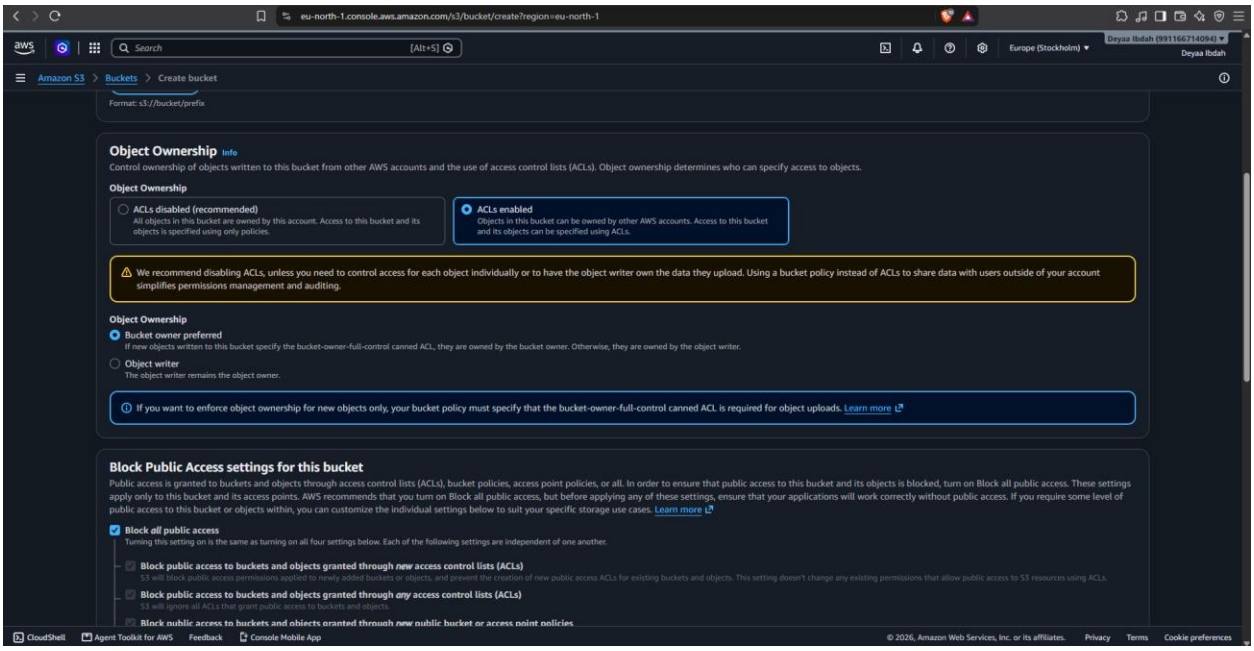

Select create bucket to create S3 bucket and we will use it to host a static website, after that we need to name our bucket

After chose the bucket name head to object ownership and chose ACL's enable

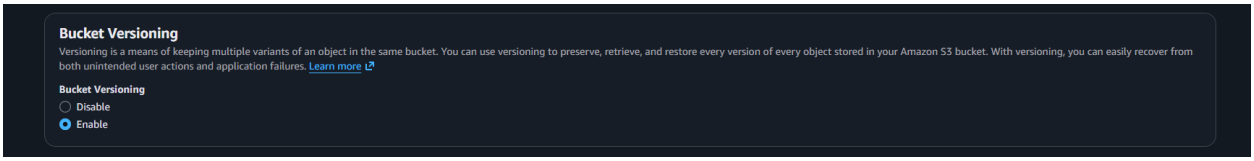

Enabling ACLs in this S3 setup lets you control who can access and do things with the objects (i.e. website files) you upload into your bucket.

With ACLs, different AWS accounts can own and control different files in your bucket.

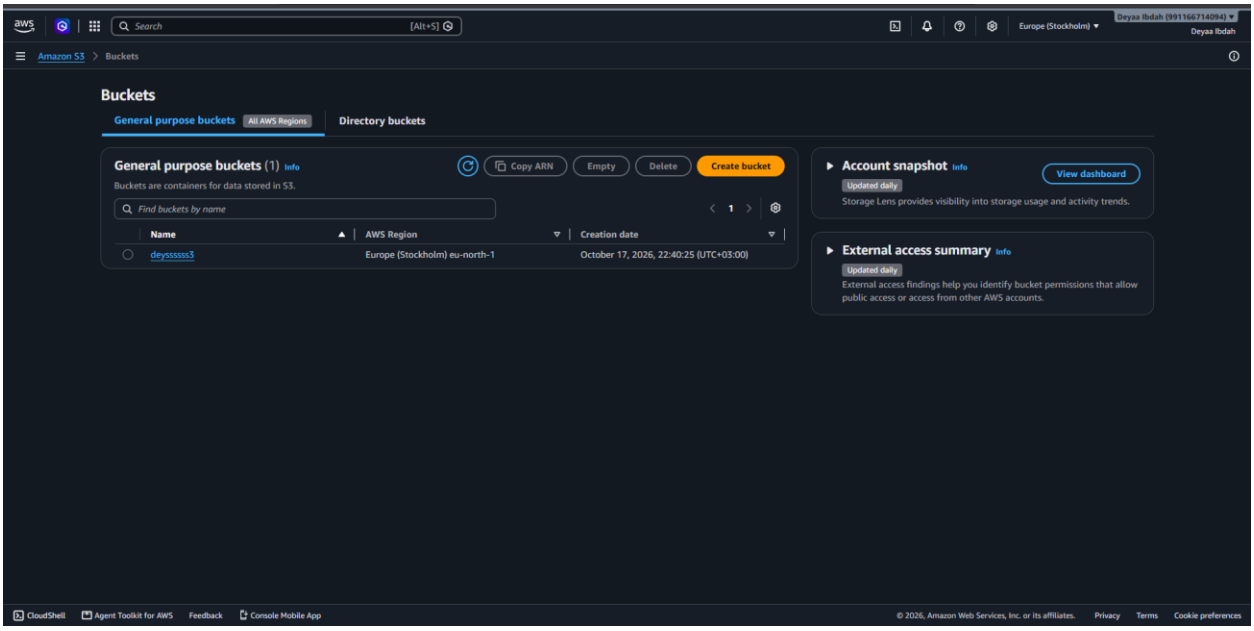

Choose Bucket owner preferred.

For Block Public Access settings for this bucket, clear the check box for Block all public access and check the box that says **“I acknowledge that the current settings might result in this bucket and the objects within becoming public.”**

and enable **Bucket Versioning** then create bucket

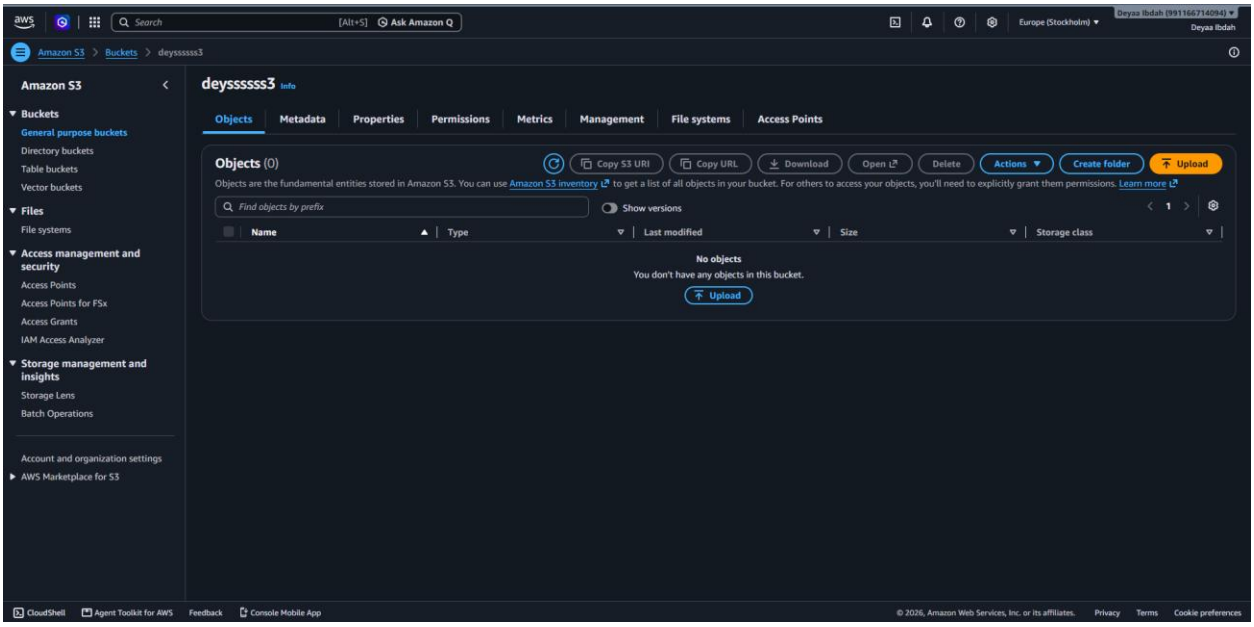

after that we will find that we created our first bucket

Phew, that's our S3 bucket all created.

Time to get those website's files inside your bucket!

In the **Buckets** section, choose the name of your new bucket.

Return to the Amazon S3 console with your bucket page open.

Choose the Objects tab Objects.

Choose Upload.

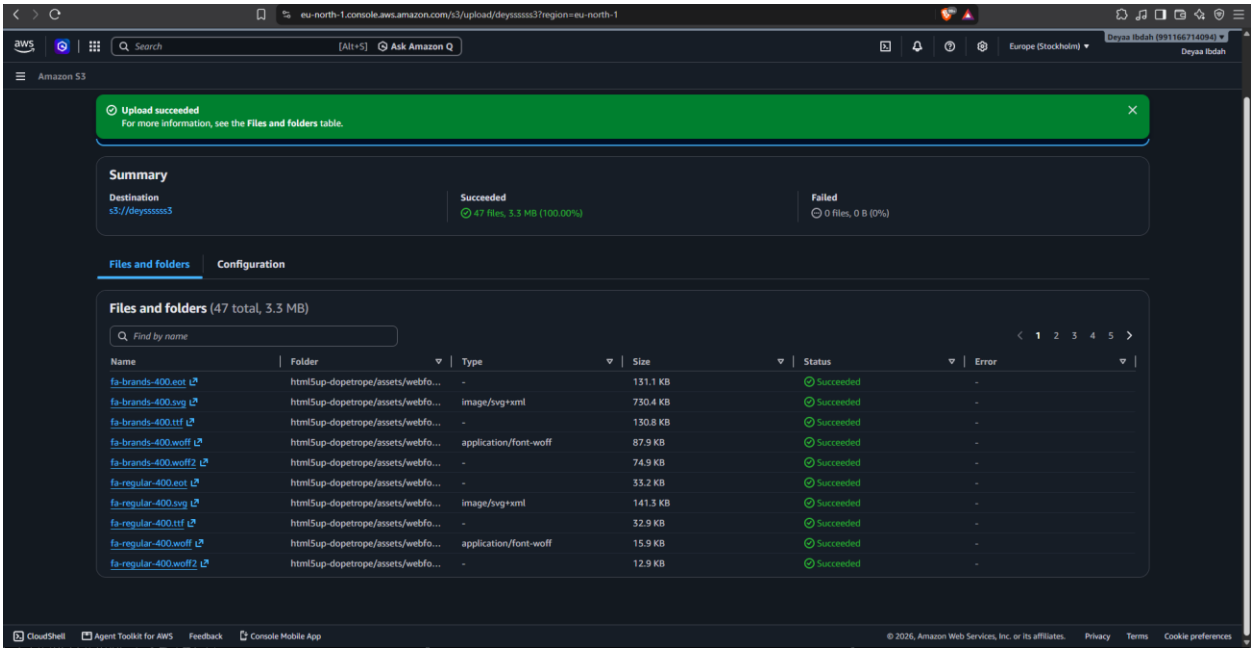

Choose Add files.

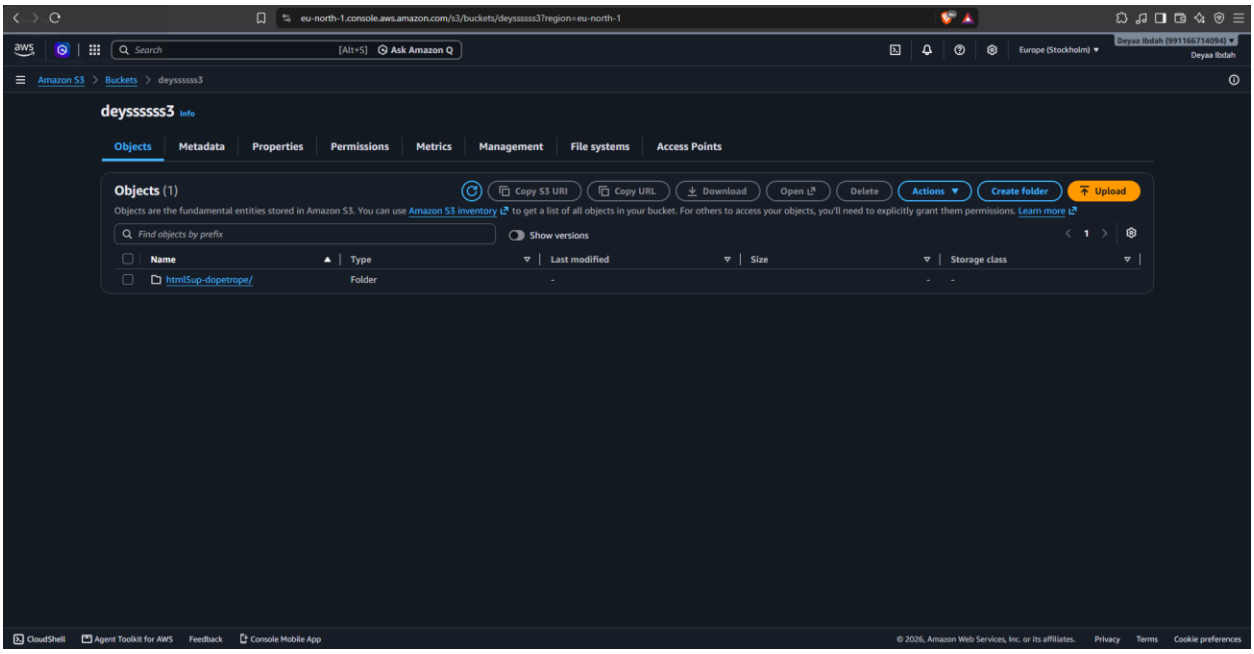

Choose index.html.

Choose Add folder.

Choose the unzipped folder - NOT the zip file itself! You might get a popup that tells you that all files in that folder will be uploaded ("Do you want to upload 44 files?").

Select Upload if you need to! Choose Upload in your AWS console.

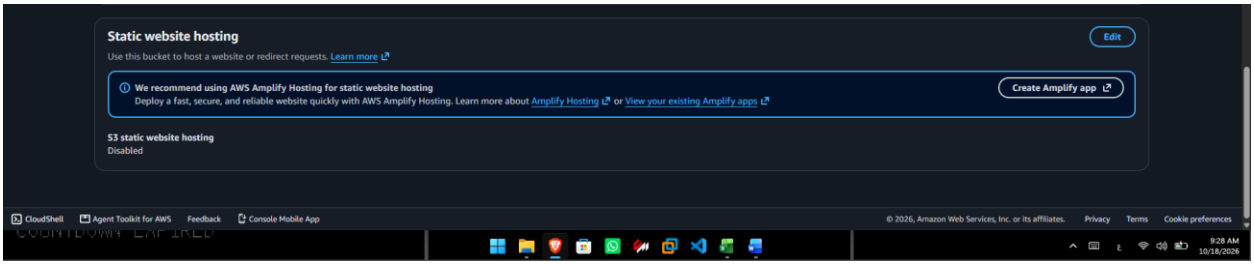

Make sure you're back in your bucket's page. If you're not sure, choose General purpose bucckets on the left hand side navigation bar, and then choose the bucket you created for this project.

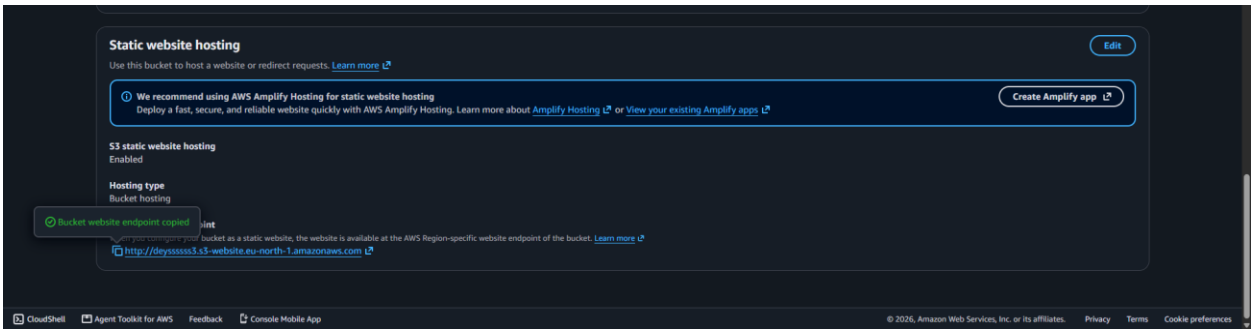

Choose the Properties tab.

Scroll allllllllll the way down to the Static website hosting panel.

Choose Edit.

After enable we will get **Bucket website endpoint**

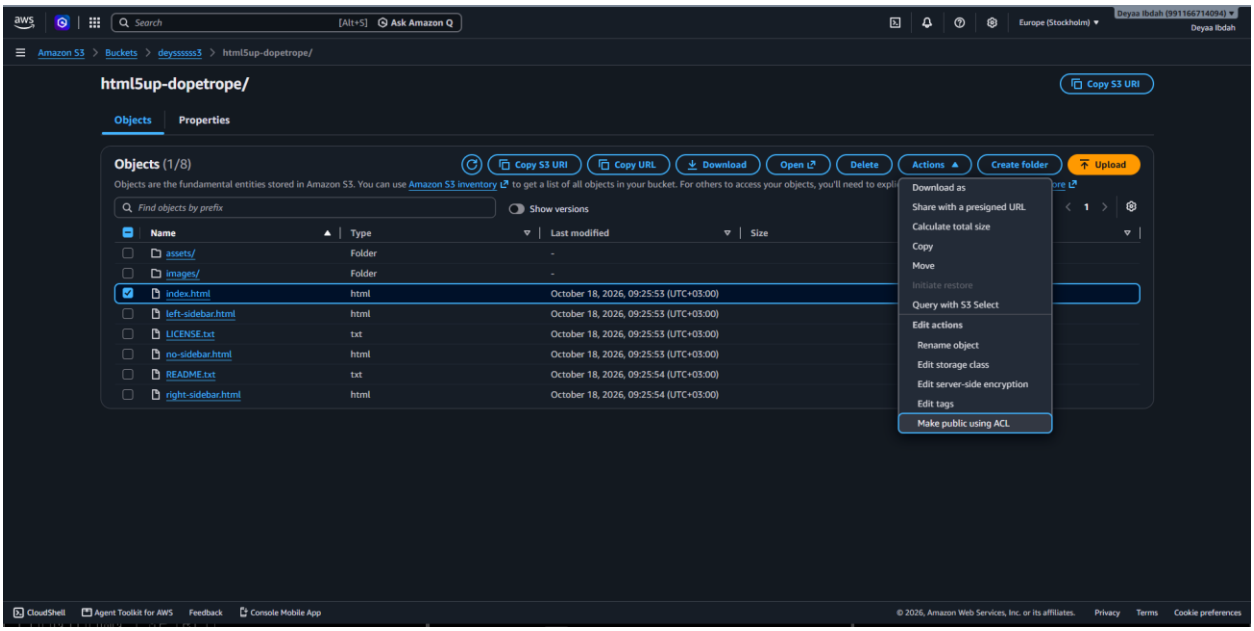

We will see error massage

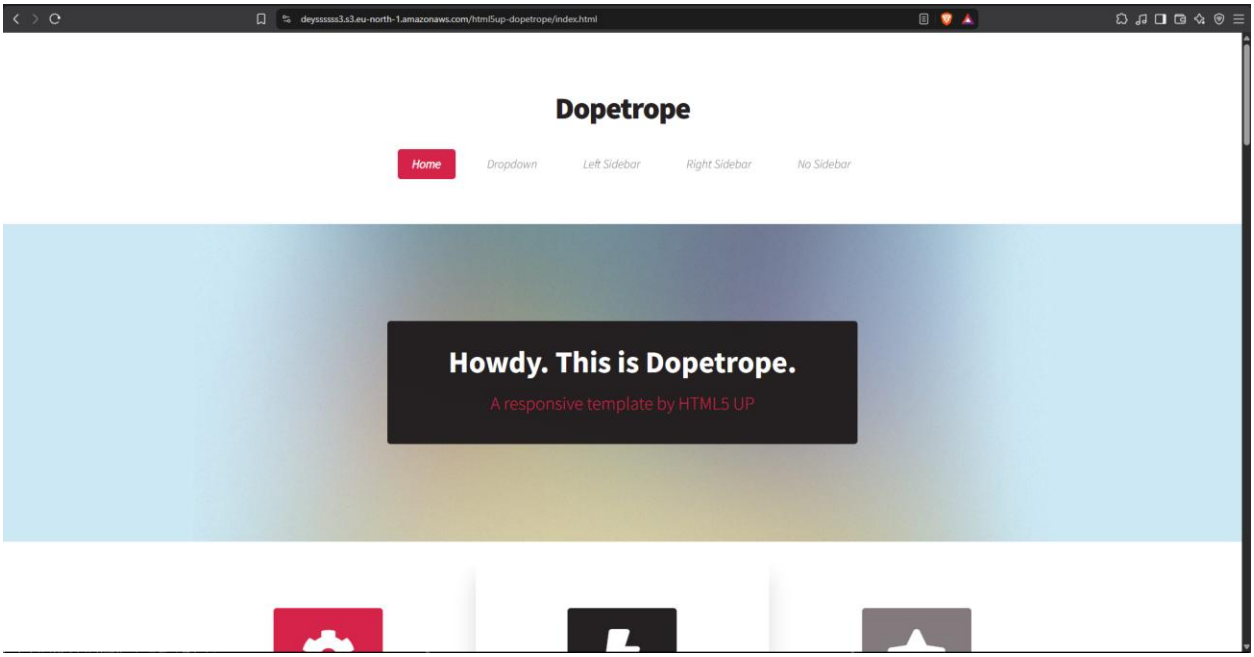

Why did I get this error? Objects (in this case, the HTML and images files you uploaded) are private by default. This default setting helps keep your account's data secure. The error message you're seeing is telling you that your static website is being hosted by S3, but the actual HTML/image files you've uploaded are still private. It's kind of like having a bucket on display, so everyone can see the bucket - but the contents are covered up, preventing anyone from seeing what's inside. To solve this error, we need to set the permission of the objects to public - this is why we enabled ACLs in first task

then we will make our website files in S3 publicly accessible.

Step 4: Enable Static Website Hosting

Opened the S3 bucket's Properties tab and enabled Static Website Hosting. Configured the index document and retrieved the website endpoint to test access to the hosted website.

Verify the Deployment

After adjusting the object permissions for this public website demonstration, I reopened the S3 website endpoint and confirmed that the static website loaded successfully.
